ABSTRACT

Objectives There are more than 7000 rare diseases in the USA, and they are prevalent in 8% of the population. Due to life-threatening risk and limited therapies, early detection and treatment are critical. The purpose of this study was to explore characteristics of visits for patients with rare diseases seen by primary care physicians (PCPs).

Design The study used a cross sectional study using a national representative dataset, the National Ambulatory Medical Care Survey for the years 2012–2014.

Setting Primary care setting.

Participants Visits to PCPs (n=22 306 representing 354 507 772 office visits to PCPs).

Primary outcome measures Prevalence of rare diseases in visits of PCPs was the primary outcome. Bivariate analyses and logistic regression analyses were used to compare patients with rare diseases and those without rare diseases and examined characteristics of PCP visits for rare diseases and practice pattern.

Results Among outpatient visits to PCPs, rare diseases account for 1.6% of the visits. The majority of patients with rare diseases were established patients (93.0%) and almost half (49.0%) were enrolled in public insurance programmes. The time spent in visits for rare diseases (22.4 min) and visits for more common diseases (21.3 min) was not significantly different (p=0.09). In an adjusted model controlling for patient characteristics (age, sex, types of insurance, reason for this visit, total number of chronic disease, having a rare disease and established or new patient), patients with rare diseases were 52% more likely to be referred to another provider (OR 1.52, 95% CI, 1.01 to 2.28).

Conclusions Visits for rare diseases are uncommon in primary care practice. Future research may help to explain whether this low level of management of rare diseases in primary care practice is consistent with a goal of a broad scope of care.

INTRODUCTION

Primary care physicians (PCPs) are trained to provide care for a broad scope of conditions within their patient population. When PCPs maintain a broad scope of practice this safeguards access and quality of care for the general population. Some of these conditions are managed directly by the PCP and

Strengths and limitations of this study

- This study is the first research to investigate characteristics of patients with rare diseases seen in primary care practice and the association between physician referral and rare disease diagnosis.
- The study used population-based national representative data allowing for generalisability.
- Primary care physicians may play a vital role in providing continuous care and managing patients with rare diseases effectively.
- The study is limited to the actions recorded in one visit due to study design.
- The study was unable to determine if that referral is for a consult or part of a shared care relationship between primary care and specialty care.

with others the PCP coordinates the care for the patient. One recent study indicated that in 1 year, family physicians typically manage about 1700 diagnoses in office visits, with 100 diagnoses managed frequently.¹

In addition to common, high prevalence diseases like diabetes, hypertension and arthritis, a substantial proportion of the general patient population, has a rare disease, or diseases. As of 2017, the National Institute of Health Genetic and Rare Disease (GARD) Information Center had identified 7000 rare diseases, affecting approximately 25–30 million people in the US population.² Rare diseases are categorised as life-threatening, with only few limited effective therapies available. In addition to the emotional and physical burden associated with diagnosis, patients with a rare disease often face financial burden due to the significant cost associated with drugs and therapies. As such, early detection and treatment are critical. For example, in one study, more than half of patients with rare diseases being seen at a PCP practice had been diagnosed with rare diseases at a PCP practice.³

However, to date there have been few studies investigating the role of PCPs in the

management of patients with rare diseases. The purpose of this study was to examine in a nationally representative sample of visits, the prevalence of rare diseases cared for in primary care practice as well as characteristics of patients and providers.

METHODS

This study used the National Ambulatory Medical Care Survey (NAMCS), a national representative dataset, for the years of 2012 to 2014. The NAMCS is a national probability sample survey of ambulatory medical care visits to office-based physicians that allows for national estimates regarding medical care in the USA.³ Non-federally employed physicians defined by the American Medical Association and the American Osteopathic Association who were principally engaged in patient care activities and who are not specialised in anaesthesiology, pathology and radiology were eligible. Also physicians who are younger than 85 years of age at the time of the survey were eligible. Based on multistage probability design, eligible PCPs were selected and informed about the survey and those who agreed to participate to the survey were included in the data.³ NAMCS data are collected annually by the National Center for Health Statistics (NCHS). It is electronic record collected by the Census Bureau in the USA and multiple steps were implemented to process and review the data based on the NCHS protocol. The data estimates to be reliable met two criteria, (1) sample records should be at least 30, and (2) a relative SE should be 30% or less.³ The sample frame for NAMCS data in the years 2012–2014 was composed of PCPs who specialise in primary care (eg, general and family practice, internal medicine and paediatrics), and who identified themselves as the PCP of the patient.⁴ This list conforms to the definition used by the NAMCS to categorise primary care. Diagnosis was determined based upon the International Classification of Diseases (ICD)-9 codes and the diagnosis made by a PCP at a visit was electronically recorded in the patient record form. The patient report form provided pre-existing conditions, current diagnosis and new diagnosis.⁵ Thus, more than 30 diagnoses can be managed via this report form.⁶ Furthermore, this report form allows us to identify established patients who have visited before whereas it does not allow us to estimate numbers of previous visits. The unweighted sample size was 22 306 representing 354 507 772 office visits to PCPs in the USA from 2012 to 2014.

Rare disease

A rare disease is defined as a disease or a disorder that affects fewer than 200 000 people in the USA.^{2,7} For this study, diagnoses were identified as a rare disease using the list provided by the GARD Information Center.² Two independent researchers (ie, Dr Jo and Larson) and one family medicine physician (ie, Dr Carek) reviewed all new diagnosis in designated study years and identified rare diseases by comparing the list of GARD. With

consensus agreements, rare diseases for the study were determined.

Independent variables

Demographics of patients seen by PCPs, such as age, gender and race/ethnicity, were used. Gender and race/ethnicity (ie, non-Hispanic White, non-Hispanic Black, Hispanics and Others) were considered categorical variables whereas age was used as a continuous variable. In addition, their form of health insurance, major reason for the visit and total number of diagnosed chronic diseases were included as categorical variables. Health insurance was stratified into four categories: private insurance, public insurance such as Medicaid and Medicare, self-pay and others. Major reason for the visit was also categorised into four groups: new problems, chronic problems, presurgery or postsurgery care and preventive care.

Providers' characteristics including practice location (ie, urban or rural), referral to other providers (ie, yes or no) were examined. Time spent with providers in primary care setting was compared between patients with rare diseases and those without rare diseases. Time spent with providers in primary care is the length of the time the provider spent with the patient at the office and patient's waiting time to see the provider, receive care from providers and prepare for a patient such as reviewing medical chart or physical examination were excluded.³

Statistical analysis

To account for the complex survey design used in the NAMCS, a weighted variable was used to consider survey design effect. This allows for us to provide national estimates of USA ambulatory healthcare visits to office-based physicians and community health centres.³ Also, it allows us to produce national estimates of the ambulatory healthcare use in the USA.³ The prevalence of rare disease seen in the primary care office visit was estimated. X^2 tests were used to compare characteristics of PCPs who care for rare diseases against those who do not. Logistic regression was also employed to examine the association between PCP referral to other providers and patient diagnosis of a rare disease. All analyses were conducted in SAS V.9.4.

Patient and public involvement

Patients and/or public were not involved in this study.

RESULTS

The final sample was 22 306 representing 354 507 772 office visits to PCPs in the USA from 2012 to 2014. A total of 1508 PCPs participated to submit data for sample patient visits. Of the total patient visits to a PCP, a rare disease was noted in 1.6% of those visits. PCPs cared for 177 different rare diseases. Patients with rare diseases were significantly older than those without rare diseases (age difference=8.3 years, $p<0.01$), while no significant differences were found in the distribution of sex and race/ethnicity (table 1). The majority of patients with rare diseases

Table 1 Characteristics of patients with rare diseases in primary care, National Ambulatory Medical Care Survey 2012–2014 (unweighted n=22 306, weighted n=354 507 772)

	Patients with rare diseases (%)	Patients without rare diseases (%)	P value
Unweighted sample size	363	21 943	
Weighted sample size	5 581 791	348 925 981	
Mean age (years)*	47.7	39.4	<0.001
Sex			
Female	56.4	53.8	0.44
Race			
Non-Hispanic White	75.0	70.6	0.54
Non-Hispanic Black	8.6	10.1	
Hispanics	11.7	14.3	
Others	4.7	5.0	
Insurance types			
Private insurance	49.3	54.6	0.15
Public insurance	47.3	40.0	
Self-pay	1.8	3.5	
Other	1.5	1.9	
Major reasons for this visit*			
New problems	33.7	42.6	0.002
Chronic problems	39.0	28.7	
Presurgery/postsurgery	27.3	28.7	
Preventive care	0.0	0.0	
Total number of chronic diseases*	1.3	1.0	0.001

*Statistical significant level at 0.05.

were established patients (93.0%), having been seen by the PCP more than one time, and almost half (49.3%) were enrolled in private insurance programmes. Of the visits for patients diagnosed with a rare disease, 39.0% visited their PCPs with a comorbid chronic problem. In addition, they had a significantly higher total number of chronic diseases compared with patients without rare diseases ($p<0.01$) (table 1).

Of visits by patients with rare disease, 14.3% were referred to other providers (table 2). While PCPs spent slightly more time with their patients who had rare diseases (22.4 min), compared with patients without rare diseases (21.3 min), it was not significantly different (table 2). The majority of visits for patients with rare diseases and more common diseases who were seen by PCPs were located in urban areas. PCPs practising in rural areas (7.6%) were not significantly less likely than PCPs practising in urban areas (16.8%; $p=0.06$) to refer patients with rare diseases to another physician. In a bivariate analysis, care for rare

Table 2 Practice characteristics of primary care physicians who care for patients with rare diseases using National Ambulatory Medical Care Survey, 2012–2014

	Patients with rare diseases	Patients without rare diseases	P value
Practising area			
Urban	84.5	86.4	0.32
Rural	15.5	13.6	
Referral to other providers*			
Yes	14.3	9.0	0.01
No	85.7	91.0	
Time spent with providers (min)	22.4	21.3	0.09

*Statistical significant level at 0.05.

disease was also not associated with rurality ($p=0.32$) (table 2).

In an unadjusted regression model, patients with rare diseases were 69% more likely to be referred to other providers than those without rare diseases. After controlling for covariates, such as patients' characteristics (ie, age, sex, race/ethnicity, types of insurance, major reason for this visit, total number of chronic disease, having a rare disease and established or new patient), patients with rare diseases were 52% more likely to be referred to another provider than those without rare diseases (table 3).

DISCUSSION

This study found that few patients with a rare disease were identified as being managed in primary care practice. Patients with rare diseases in the primary care setting show significantly older and have more comorbidities compared with those without a rare disease diagnosis whereas patients with rare diseases are comparable to those without rare diseases in terms of sex distribution, race/ethnicity and types of health insurance. Not

†Controlled for age, gender, race/ethnicity, types of insurance, major reason for this visit, total number of chronic disease, having a rare disease and established versus new patient.

surprisingly, visits in primary care for patients diagnosed with rare diseases are more likely than patients without rare diseases to lead to referral to another provider. To our knowledge, this is the first study to investigate characteristics of patients with rare diseases seen in primary care practice and the association between physician referral and rare disease diagnosis.

Much of medical practice and the corresponding comfort in diagnosing and treating conditions is affected by the frequency of occurrence of the condition and pattern recognition. Rare diseases are by their very nature uncommon and thus PCPs may not always feel comfortable with the nuances of treatment and potential complications for a disease that they encounter very infrequently. According to the National Academy of Medicine, since rare diseases tend to accompany multiple common conditions, it disrupts a clinician's ability to recognise clues of rare diseases.⁸ In many of these cases PCPs need more than a consult from a specialist, especially when the primary care team does not have the specialised medical knowledge. Receiving all of their care from specialists may not be the best situation for the patient. Patients with rare diseases need to be managed in primary care or at least have shared care between primary care and specialists in complementary roles to provide a more effective management of these complex patients.

There are some limitations to this study. First, due to the design of the NAMCS we are limited to the actions recorded in that one visit. The design does allow us to have an understanding of the types of patients seen in primary care but it is not data on a cohort of patients. Thus, we do not know what sort of care may have transpired between the patient and the physician in previous visits. Also, it is not able to explore the linkage of multiple consultations with specialists previsit or postvisit to PCPs. Second, we are able to see if patients are referred in that one visit, we are unable to determine if that referral is for a consult or part of a shared care relationship between primary care and specialty care.

CONCLUSION

This study identified characteristics of patients with rare diseases who are seen in primary care practice and the delivery patterns of PCPs managing patients with rare

diseases. Findings from this study suggest that PCPs must possess a broad scope of practice in order to deliver comprehensive, high-quality care. A better understanding of the overall management of patients with rare diseases managed solely outside of primary care would help to improve the care for these patients.
