Developing the Network Pain Rehabilitation Limburg: a feasibility study protocol

Cynthia Lamper, Mariëlle Kroese, Albère Köke, Dirk Ruwaard, Jeanine Verbunt, Ivan Huijnen

ABSTRACT

Introduction Patients having chronic musculoskeletal pain (CMP) face challenges as mismatches often exist between the complexity of patient's pain problem and the rehabilitation treatment offered. This can result in less efficient care for the patient and increased medical shopping. The Network Pain Rehabilitation Limburg (NPRL), a transmural integrated healthcare network, will be designed to improve daily care for patients with CMP. NPRL focusses on improving patient's level of functioning despite pain by stimulating a biopsychosocial approach given by all involved healthcare professionals. A feasibility study will be performed which will give insight into the barriers and facilitators, perceived value, acceptability and implementation strategies for NPRL.

Methods and analysis This study has a three-phase iterative and incremental design, based on key principles of a user-centred design. Mixed methods will be used in which healthcare professionals and patients involved in NPRL will participate. In phase 1, NPRL will be developed and healthcare professionals educated. Phase 2 focusses on the implementation and phase 3 on the transferability of NPRL. In addition, preliminary data on patient's work status, general health and participation level will be collected. The qualitative results of each phase will be analysed following the Consolidated Framework for Implementation Research (CFIR) and will be used to refine NPRL in daily practise.

Ethics and dissemination Informed consent will be obtained from all participants. The results of this feasibility study will form the basis for refinement of NPRL and planning of a large-scale process and effect evaluation of the Quadruple Aim outcomes. Dissemination will include publications and presentations at national and international conferences. Ethical approval for this study was granted by the Medical Ethics Committee Z, the Netherlands, METC 17 N-133.

INTRODUCTION

Nineteen per cent of adults in Europe suffer from moderate to severe chronic pain with a duration of at least 6 months according to a large-scale epidemiological study. Also, about 18% of adults in the Netherlands have moderate to severe general chronic pain. Almost 90% of individuals with chronic pain had experienced it for over 2 years. The most reported chronic pain complaint was chronic musculoskeletal pain (CMP). CMP is a complex biopsychosocial experience that varies widely between people depending on the context and meaning of the pain and the impact of psychosocial factors on patient's functioning.

Breivik et al found that people with CMP were less able or even unable to do a range of daily activities and to maintain an independent lifestyle. In addition to pain itself, patients with CMP are often confronted with an elevated level of disability, depression and anxiety resulting in an increased disease burden. In addition, work absenteeism among these patients is very high. In recent years, the direct and indirect costs for patients with CMP are estimated at 20 billion euros in the Netherlands. These costs...
are even higher than the annual costs of heart disease, cancer and diabetes.\textsuperscript{12} Although costs for CMP are high, only up to 60\%–74\% of patients with CMP get treated, and only 2\%–5\% get treated by a pain management specialist.\textsuperscript{1, 2, 13} Currently, regardless of the treatment received, 34\%–79\% of Dutch patients with CMP still indicate a feeling of inadequate treatment.\textsuperscript{14} These patients seek a diagnosis or solution to their pain problem, which explains medical shopping. Even 61\% of patients that started a multidisciplinary rehabilitation programme visited 6 to >20 different healthcare professionals 1 year before starting with multidisciplinary rehabilitation programme.\textsuperscript{15} A potential reason for these inefficiencies might be that the complexity of the patient’s pain problem does not match with treatment as delivered, resulting in overtreatment or undertreatment,\textsuperscript{16} which highlights the need for adequate (cost) effective treatment strategies.

This mismatch may be explained by the fact that the knowledge and perspective of healthcare professionals, decision makers and the public varies regarding CMP, referral and treatment.\textsuperscript{15} Healthcare professionals receive inadequate training on the diagnosis and treatment of CMP, causing different points of view.\textsuperscript{15} Some healthcare professionals are more biomedical oriented and focus on explaining and solving the pain, whereas others are more biopsychosocial oriented and focus on optimising functioning despite CMP.\textsuperscript{18} Therefore, referral and treatment selections vary among healthcare professionals, which may result in less efficient care for patients with CMP.

Besides the different perspectives regarding CMP, general practitioners (GPs) in primary care and rehabilitation physicians (RPs) in secondary and tertiary care refer patients mostly based on their anamnesis and clinical experience. However, it appears to be difficult for GPs to identify the impact of all psychosocial factors on patients with chronic low back pain, one of the most frequently encountered CMP problems.\textsuperscript{19} Recently, different tools became available to support GPs in the decision-making process concerning (initial) treatment options for patients with chronic low back pain and fibromyalgia, especially focusing on the impact of psychosocial components.\textsuperscript{20-25} However, these decision-making tools are not implemented in daily care yet in the Netherlands. In the Dutch healthcare system, patients with moderate to severe levels of disability and associated influencing psychosocial factors are seen by an RP. To support decision making by RPs, an evidence-based objective tool to classify patients objectively and transparently for a specific treatment is needed. Earlier studies have shown that the inter-rater reliability of the method currently used by RPs to classify the level of disability (WPN classification) is at least questionable.\textsuperscript{24, 25} In addition, healthcare professionals indicate a lack of overview regarding the complete supply of treatment methods, resulting in inadequate referrals.\textsuperscript{26}

Ideally, after assessing the level of disability, the patient receives a treatment matching the complexity of the pain problem in line with the biopsychosocial profile. As in most situations, no cure for CMP is possible and evidence-based treatments are multicomponent pain rehabilitation with a biopsychosocial focus on being active and living a valuable life despite pain.\textsuperscript{5, 27-29} In primary care physiotherapy, cognitive–behavioural interventions and interventions focusing on biopsychosocial factors have shown long-term effects on patient outcomes.\textsuperscript{30, 31} Moreover, even positive effects were found when advice combined with pain education alone is given by GPs or therapists to patients with CMP.\textsuperscript{32-34} In secondary and tertiary care, multidisciplinary pain rehabilitation programmes with physical, psychological and/or social/work-related components, like Acceptance and Commitment Therapy (ACT), Graded Activity (GA) and Exposure in vivo (EXP), are more effective than treatments focusing on one aspect of the biopsychosocial model for decreasing pain and disability in patients with disabling chronic low back pain.\textsuperscript{35-40}

Despite this knowledge of the effective components of multidisciplinary rehabilitation programmes, a wide variety of treatment approaches in various dosages are currently applied in regular rehabilitation programmes in different private and public rehabilitation centres.\textsuperscript{31} To overcome the different points of view as well as the lack of overview about treatment options, objective decision-making tools and variety of treatments in the Netherlands, a national care standard for chronic pain was presented in 2017.\textsuperscript{11} In this standard, a matched and person-centred care approach for patients with CMP was proposed.\textsuperscript{42}

To implement care as part of the national care standard, a transmural network could be designed in which different healthcare professionals collaborate in providing person-centred rehabilitation care. Recently, different transmural integrated care health networks, for example, for Parkinson’s disease and palliative care, have been successfully developed and implemented in the Netherlands.\textsuperscript{43, 44} In line with these findings, a transmural pain rehabilitation network can provide a shared vision regarding CMP. It will include early recognition of patients with subacute pain followed by suitable person-centred treatment and referral. The treatment within the network is supposed to improve patients’ levels of functioning despite pain and to prevent medical shopping of patients with CMP.\textsuperscript{11} It should have an unambiguous view, matched care and a person-centred approach with guidelines for referral and treatment, coordination and a continuous focus on improvement of care to increase the effectiveness, quality and efficiency of healthcare for patients with CMP.\textsuperscript{45} This approach fits with the advice of the WHO to focus on stimulating functioning when designing rehabilitation care.\textsuperscript{46, 47}

The Network Pain Rehabilitation Limburg (NPRL), a transmural healthcare network for CMP rehabilitation, will be designed to ultimately fulfill the Quadruple Aim in the province of Limburg, the Netherlands.\textsuperscript{48, 49} NPRL provides integrated care for patients with CMP in order to improve their level of functioning despite pain by stimulating a biopsychosocial approach for all involved
healthcare professionals. As a first step, a feasibility study will be performed. This study aims to provide insight into the barriers and facilitators, perceived value, acceptability and implementation strategies for the development, implementation and transferability of the NPRL. This paper describes the study protocol of the feasibility study of NPRL for adults with CMP.

**METHODS**

**Study design**

A feasibility study with an iterative and incremental design, based on key principles of user-centred design, will be conducted in the South-East region of the Netherlands from October 2017 until October 2018. This will follow the UK Medical Research Council framework for developing complex interventions. It will be useful as NPRL is a complex intervention because of the number of practices and integrated healthcare settings targeted in the NPRL and the number and variability of outcomes. In this iterative process, the development of NPRL will take place in three phases, namely development, implementation and transferability. The results of each phase will be used to refine the elements of the intervention and to shape the next phase, in which the barriers and facilitators of the different phases will be evaluated. During meetings, all healthcare professionals involved will be informed about the results and the adjustments to NPRL. In the subsequent phase, new adjustments will be integrated in daily practice. The development and implementation process will be ‘practise-focused’, indicating that the development will be based on the healthcare professionals’ experiences with the current healthcare situation.

In phase 1, exploration of context will take place in order to develop the design of the NPRL and to educate the healthcare professionals involved. The focus will be on the barriers and facilitators in the development process of NPRL. Next, in phase 2 (implementation), the project focus will be on the specification of the content to adjust the design of the NPRL to daily practice. More insight into the barriers and facilitators of the implementation process will be collected. In phase 3 (transferability), the project will focus on the organisation of care in daily practise and the research focus will be on the barriers and facilitators for further implementation in other practices and organisations. In addition, preliminary data on efficiency will be collected. The qualitative data collected during the study will be analysed using the Consolidated Framework for Implementation Research (CFIR). NPRL will be feasible in daily practice if the studied barriers and facilitators from the perspectives of healthcare professionals and patients are translatable to policies or guidelines that can be adjusted and integrated in daily practise.

**Participants**

In this transmural NPRL, healthcare professionals from different disciplines (GPs, physiotherapists, exercise therapists, mental health practice nurses, RPs and rehabilitation teams) and different healthcare settings (primary, secondary and tertiary care) will be asked for participation. In primary care, the recruitment will start with a primary care therapist or a GP interested in pain, and after consent to participate in NPRL. This person will be asked to recruit a GP or therapist with whom they already have intensive collaboration. For secondary and tertiary care, main organisations in the region providing rehabilitation care for patients with CMP will be asked for participation. In phase 1, exploration of context will take place in order to develop the design of the NPRL and to educate the healthcare professionals involved. The focus will be on the barriers and facilitators in the development process of NPRL. Next, in phase 2 (implementation), the project focus will be on the specification of the content to adjust the design of the NPRL to daily practice. More insight into the barriers and facilitators of the implementation process will be collected. In phase 3 (transferability), the project will focus on the organisation of care in daily practise and the research focus will be on the barriers and facilitators for further implementation in other practices and organisations. In addition, preliminary data on efficiency will be collected. The qualitative data collected during the study will be analysed using the Consolidated Framework for Implementation Research (CFIR). NPRL will be feasible in daily practice if the studied barriers and facilitators from the perspectives of healthcare professionals and patients are translatable to policies or guidelines that can be adjusted and integrated in daily practise.

In primary care, the recruitment will start with a primary care therapist or a GP interested in pain, and after consent to participate in NPRL. This person will be asked to recruit a GP or therapist with whom they already have intensive collaboration. For secondary and tertiary care, main organisations in the region providing rehabilitation care for patients with CMP will be asked to participate, so all healthcare settings in this region will be covered. Because of the nature and aim of this feasibility study, we decided to keep the number of healthcare professionals restricted. Based on earlier research, it has to be expected that, in this situation, the implementation process in daily practice can be easily adjusted when barriers arise.

In addition to the involvement of healthcare professionals in this study, all patients treated by the participating healthcare professionals will be asked to evaluate NPRL and the perceived quality of care. The inclusion criteria for patients to participate in this study are described in table 2.

---

**Figure 1** Construction of the healthcare system in Network Pain Rehabilitation Limburg.
It is expected that approximately 100 patients from all participating healthcare settings will give informed consent during the course of this study. They will receive questionnaires regarding satisfaction with care and their health status and pain-related disability. Moreover, a sample of approximately 10 patients, who finished a treatment according to the protocol of NPRL, will be recruited for a focus group. In this focus group, more information about barriers and facilitators from a patient perspective will be collected. In this way, patients are able to react to each other which will illuminate various perspectives which leads to a faster data saturation about each topic, which is an advantage above interviews.54

**Intervention: NPRL**

The main aim of NPRL is to provide integrated care for patients with CMP in order to improve their level of functioning despite pain by stimulating a biopsychosocial approach for all involved healthcare professionals. This should accomplish the Quadruple Aim: improvement of CMP patient functioning, experiences of care and work–life satisfaction of physicians and staff, as well as a reduction of healthcare costs of patients with CMP.

Each patient will receive the treatment needed to reach his/her optimal level of functioning. In order to reach this, a matched care approach will be used for every individual patient. Depending on the level of disability and biopsychosocial factors involved, this will either include (1) education only and no further treatment, (2) monodisciplinary treatment in primary care, (3) multidisciplinary treatment in primary care (collaboration between GPs, primary care therapists and mental health practice nurses in assessing and treating patients with CMP who need mental support besides physical exercise), (4) interdisciplinary treatment in secondary or (5) interdisciplinary treatment in tertiary care. Collaboration will be supported by facilitating communication between patients and all healthcare professionals involved in the trajectory of an individual patient by E-health.55 In addition, the collaboration between healthcare professionals in different practices and organisations will be further supported by informative meetings and education days. All healthcare professionals with different specialisms will participate together in the meetings and education days. This ensures a common understanding of the

GP, general practitioner; NPRL, Network Pain Rehabilitation Limburg; RP, rehabilitation physician.
biopsychosocial approach and rehabilitation treatment options. In order to facilitate this in daily practice, the following elements are integrated in NPRL.

Integral focus on assessment and referral: assessment tools

To support the healthcare professionals in their decision making for problem mapping and treatment selection, two evidence-based objective assessment tools will be used. These tools will support the assessment of the complexity of the pain problem; one tool for GPs and primary care therapists and one tool for RPs. The assessment tool for primary care is based on the Start Back Tool and will help to advise patient treatment matched to the patient’s biopsychosocial profile. The options are: advice only, treatments in primary care or for decision making by a RP. The GP can also decide to advise patients for a treatment outside NPRL (psychiatrist, specific healthcare specialist, etc). Since 2006, patients in the Netherlands can visit a primary care therapist without a referral of a GP, so these therapists will also use this assessment tool. In this situation, a primary care therapist of NPRL will advise the patient to visit the GP for additional assessment and referral if needed as the GP is the gatekeeper to secondary and tertiary care.

When a patient visits an RP, the assessment tool for specialised rehabilitation care is used for decision making. This tool will assess the patient’s view as well as the RP’s view of the biopsychosocial problem and consists of two parts. The first part will guide the anamnesis of the RP and is based on two different ways to score disability-related complexity, namely the Case Complexity Index and INTERMED method. First, a standardised scoring method for assessing the biopsychosocial profile and care for the past and current situations will be used by the RP. Second, a set of CMP-related questionnaires assessing anxiety, depression, catastrophising, fatigue, pain level, participation level and general health will be completed by the patient. After completion of these questionnaires, scores will be interpreted by the RP. Based on scoring in both parts of the RP assessment tool, patients will be categorised by profile, representing the patient’s level of disability. In addition to primary and interdisciplinary primary care, the second tool will assist the RP to further differentiate between available secondary or tertiary multidisciplinary rehabilitation programmes.

Integral focus on treatment content and duration: treatment protocols

When the patient receives treatment, an individualised treatment plan based on their current needs will be made. The patient decides the treatment aim when he visits a healthcare professional. In case this is necessary, the practitioner will support the patient in setting functional goals. Protocols will be based on the most recent evidence-based treatment methods such as GA, EXP and ACT and these will be used in all healthcare settings. As these evidence-based methods are developed for secondary and tertiary care, they will be adjusted for primary care. During evaluations in phases 1 and 2, healthcare professionals will be invited to provide feedback on the treatment protocols. As a result, adjustments to the content and duration of treatment protocols will be...
made if these adjustments are in line with the evidence-based treatment methods.

**Integral focus on self-management: E-health application**

All professionals and patients participating in the NPRL will make use of an E-health application: SanaCoach Pain Rehabilitation. Also, primary care patients who receive ‘advice only’ can make use of this SanaCoach Pain Rehabilitation. The coach has different functions and goals in the treatment process. The primary goal is to support self-management. The main function of the coach is to provide pain education based on the education modules. Different eLearning modules are developed for the patients in order to teach them about the biopsychosocial aspects of pain. Furthermore, diaries are integrated into the coach in which patients can give feedback on changes in pain intensity, level of activity over time and the inter-relation between these variables. Moreover, healthcare professionals can use scores from these diaries to adjust treatment to individual patients. The coach also consists of a chat function between the patient and healthcare professionals to ensure short communication lines. All healthcare professionals involved in the care process of a patient have access to this chat function with that patient. Additionally, the assessment tool for primary care is integrated, which makes these results available for all involved healthcare professionals. For this study, the questionnaires for patients are also available via the coach. Based on the level of complexity of disability, the functions in the SanaCoach Pain Rehabilitation will be adjusted to the patient, such as the number of diaries and level of education.

**Patient and public involvement**

During the development of the research question, design, recruitment and conduct of the study, no patients were involved in the process. However, during the development of NPRL itself, a patient was involved in the development of the SanaCoach Pain Rehabilitation and treatment protocols. Moreover, the focus of this feasibility study is mainly on healthcare professionals. They were involved in the development of the treatment protocols, SanaCoach Pain Rehabilitation and in the development of the different communication strategies between the healthcare professionals themselves. The results of the study will be disseminated to the study participants via the webpage (www.netwerkpijnrevalidatie.nl) and social media accounts.

**Data collection**

In this study, the feasibility of the development, implementation and transferability of NPRL for adults with CMP will be investigated. Therefore, different data collection techniques such as observations, interviews, focus groups and questionnaires will be combined to get more insight into the barriers and facilitators of NPRL (table 3).

During the informative meetings and education days, field notes will be made in order to collect information about the views on NPRL and its elements out of the perspectives of the healthcare professionals involved. At the end of each phase, focus groups and/or interviews will take place with (a selection of) the healthcare professionals involved. During the evaluation of phase 1, healthcare professionals will be asked about the barriers and facilitators they perceived while working in NPRL. Therefore, more information will be collected about expectations, views, experiences and satisfaction. Also, experiences and opinions about the informative meetings and education days will be collected. Healthcare professionals will fill in an electronic questionnaire in phase 1 concerning decision making, treatments and characteristics of the patients involved in the study. This information will give more insight into potential changes in referral policy between the situation in usual care and the situation within NPRL. Moreover, the questionnaire also asks for knowledge and perspectives regarding patients with CMP.

In phases 2 and 3, more emphasis will be put on the added value of NPRL, including barriers and facilitators for implementation. This information will be used for recommendations for practise and future research. Also in these phases, information will be gained about the experiences and satisfaction with NPRL during a focus group with healthcare professionals. Moreover, in phase 3 (transferability), they will fill in an electronic questionnaire concerning decision making, treatments and characteristics of the patients involved in the study. As part of the evaluation of phase 3, a focus group with a sample of 6 to 10 patients with CMP who are being treated by participating healthcare professionals will take place. During this focus group, the emphasis will be on the satisfaction of care and experiences, leading to barriers and facilitators with NPRL.

Besides this information, the research team will keep up a logbook to get insight into the barriers and facilitators of NPRL. The field notes in this logbook will be the results of discussions with different healthcare professionals, patients and stakeholders, as well as researchers. Additionally, patients will be asked to complete study-related questionnaires about the quality and their satisfaction with the decision making, treatment and education and usability of the SanaCoach Pain Rehabilitation in order to further improve different elements of NPRL. Besides this feasibility data, also some questions about their work status, general health and participation level will be asked as preliminary data on efficiency to objectify the progress of the treatment. They will receive this questionnaire at the start of the treatment (T0) and at the end of the treatment (T2). Patients referred to another healthcare professional will receive an extra questionnaire after the referral (T1) regarding the quality of and satisfaction with the decision making. Additionally, after completion of the treatment, a small questionnaire or logbook about the treatment of each patient separately must be handed in by the healthcare professionals. This information will be used to discover barriers and
facilitators and desired adjustments of the treatment protocols.

**Data analysis**
In this iterative design with key principles of user-centred design, the results will be gathered in daily practice from the healthcare professional and patient perspective. The results of each phase will be used to adapt the intervention for the next phase. The CFIR protocol, according to Damschroder et al., will be used to develop this feasibility evaluation and analysis plan of the results. This explanatory framework with theory-based constructs and mechanisms will be used to explain whether an implementation may or may not succeed and to identify barriers and facilitators.

All field notes and logbooks will be collected. Additionally, the focus groups and interviews will be audio recorded and transcribed verbatim. Qualitative data will be analysed using the NVivo software (NVivo V.11.1.0.411) following a directed content analysis method. The analysis will be deductive (e.g., the identified themes will derive from existing theory). After familiarisation with the data, definitions for the CFIR constructs will be made based on the

intervention in collaboration with the project team. Next, the different constructs will be assigned to the fewest codes possible. After developing analytic summaries and matrices, the data will be compared with derive barriers and facilitators. A researcher with expertise in qualitative research without any involvement in the project will peer review the analysis by verification of the analysis of 20% of the interviews and focus groups. Also, a cross-check for interim findings with respondents will be performed.

Quantitative data will be analysed concurrently with the qualitative data. Descriptive statistics will be denoted as mean (SD) or median (range) and number (%) for continuous and categorical data, respectively, with the use of IBM SPSS Statistics V.24.

ETHICS AND DISSEMINATION

Informed consent will be obtained from all participants. Ethical approval for this study was granted. The results of this feasibility study will form the base for refinement of NPRL and planning of a large-scale process and effect evaluation on the Quadruple Aim outcomes. Dissemination will include publications and presentations at national and international conferences.

DISCUSSION

This study will provide insight into the feasibility of NPRL, a transmural integrated healthcare network for CMP rehabilitation. The aim is to provide integrated care for patients with CMP in order to improve their level of functioning despite pain by stimulating a biopsychosocial approach for all involved healthcare professionals. It is expected that the study will provide information on barriers and facilitators, perceived value, acceptability and implementation strategies for the development, implementation and transferability for further develop and refinement of the NPRL. If the study results suggest that NPRL is feasible and preliminary outcomes are positive, a large-scale process and effective evaluation of the Quadruple Aim outcomes will be performed.

The process of developing NPRL is in accordance with the Medical Research Council guidance on how to develop and evaluate complex interventions. In the development process, existing evidence together with collected evidence based on the expertise of healthcare professionals was combined to develop the first version of NPRL. This first version of NPRL will be implemented on a restricted scale to test the feasibility. The evidence generated from this feasibility study will not only help to adjust the design and content of NPRL but will also inform future methodological studies on developing and implementing a transmural network in healthcare. It is expected that this bottom-up development in combination with the limited number of participating healthcare professionals will lead to a successful implementation of the network. Nijkrake et al did indicate this approach as one of the success factors of ParkinsonNet, a successful and cost-effective network in the Netherlands for patients with Parkinson’s disease.

In conclusion, there is need for a transmural network in which different healthcare professionals collaborate in providing integrated healthcare for patients with CMP. The aim of NPRL is to improve the level of functioning of individual patients despite pain, experience of care by patients and work–life satisfaction for physicians and staff, as well as a reduction in costs. Therefore, this feasibility study will be conducted to explore the barriers and facilitators of the development, implementation and transferability of NPRL. The results will be applied to refine a large-scale process and effective evaluation of the Quadruple Aim outcomes.

Acknowledgements We would like to thank Miriam Tabak, as a representative of the patient organisation Pijnpatiënten naar één stem, for her contribution in the development of the SanaCoach Pain Rehabilitation Limburg and the treatment protocols. Moreover, we would like to thank Mario Gellen, physician assistant Adelante Centre of Expertise in Rehabilitation and Audiology, Hoensbroek, The Netherlands, for his contribution in the development of the treatment protocols and the education of the healthcare professionals.

Contributors JV, IH and AK conceived the original idea and outline of the study. CL, MK, IH, JV and DR contributed to designing the study. JV, IH and AK were responsible for developing the intervention. CL was the primary writer of the study protocol in collaboration with MK and IH. All authors discussed and commented on draft versions and approved the final version.

Funding This work was funded by Health Insurance Companies CZ, VGZ and Achmea, the Netherlands.

Competing interests AK, JV and IH report grants from Health Insurance Companies CZ, VGZ and Achmea, during the conduct of the study.

Patient consent for publication Not required.
