Factors other than medical acuity that influence hospitalisation: a scoping review protocol

Mellena Giday,1,2 Meghaan Hawes,1,2 Ann Madhavan,3 Maralyyssa Bann1,2

ABSTRACT

Introduction There is evidence that patients are admitted to the hospital with low-acute medical issues, though delineation of the underlying factors has not been comprehensively explored. This scoping review will provide an overview of the existing literature regarding factors outside of acute medical illness that influence hospitalisation of adults. The review will also seek to provide a review of common language and definitions used in the research on this phenomenon.

Methods and analysis The scoping review framework, outlined by Arksey and O’Malley and expanded on by Levac et al, will be used as the basis for this study. A systematic search of seven databases (PubMed, CINAHL, PsycINFO, EMBASE, Web of Science, Sociological Abstracts and Social Science Abstracts) will be conducted to identify existing literature followed by a standardised two-phase, two-reviewer process to select relevant papers for inclusion. Relevant studies will investigate adult non-psyiatric hospital admission plus at least one additional factor unrelated to medical acuity. Details of the work will be extracted, including the terminology used and perspectives included. An assessment of methodological quality will be performed using a tool designed for mixed-methods systematic review.

Ethics and dissemination The scoping review protocol delineates a transparent and rigorous review process, the results of which will be disseminated through peer-reviewed publication and presentation at relevant local or national meetings. The study does not require ethics approval as the data will be accumulated through the review of published, peer-reviewed literature and grey literature.

STUDY RATIONALE AND OBJECTIVES We aim to examine the association of factors other than medical acuity with hospitalisation. As part of our analysis, we will map the nomenclature used to define these factors, as well as research methodologies used, perspectives investigated and study results identified. By doing this, we intend to unite several bodies of work. The function of this product will be to provide a comprehensive review of the evidence base in order to identify any inconsistent use of terminology, to inform clinicians making admission decisions and policymakers or funders who review admission decisions and to expose gaps in the knowledge.

METHODS AND ANALYSIS The review will follow a standard framework for scoping reviews as delineated by Arksey
What findings have been reported? Are there any ► What type of research on factors other than medical ► Whose perspective on factors other than medical ► Which factors have been investigated with respect to ► What terminology is used to define factors other than medical acuity?

Stage 1: identifying the research questions

Because scoping reviews are intended to synthesise available evidence on a topic, the initial research question may remain broad. Levac et al suggest clarifying the focus of inquiry by identifying the purpose and intended outcome of the study.

For this review, the overarching research question being asked is: what has been studied about the relationship between factors other than medical acuity and hospitalisation of adults?

The following subquestions have been identified by study researchers to guide this work:

► What terminology is used to define factors other than medical acuity?
► Which factors have been investigated with respect to impact on hospitalisation (and, by default, which have not been investigated)?
► Whose perspective on factors other than medical acuity and hospitalisation has been investigated? (patient, physician, nurse, social worker and so on).
► What type of research on factors other than medical acuity and hospitalisation has been conducted? (epidemiological, cohort, qualitative/narrative and so on).
► What findings have been reported? Are there any factors consistently associated with hospitalisation?

Stage 2: identifying relevant studies

The second stage of the proposed scoping review will identify relevant studies for selection and data extraction. We will conduct comprehensive searches of seven databases (PubMed, CINAHL, PsycINFO, EMBASE, Web of Science, Sociological Abstracts and Social Science Abstracts). In collaboration with a medical librarian, we have developed a PubMed search strategy (see online supplementary file) utilising medical subject headings and free-text terms that retrieves 5240 results. The PubMed search has been modified to fit the database search requirements for the remaining databases. All searches will be limited to results in English involving adult subjects. No date limits will be applied. As we explore the search question, further iteration of the search may occur and will be captured by the review process. Search results will be imported into Covidence, an online systematic review management programme, and duplicates will be removed prior to the selection process.

Stage 3: selecting studies

Arksey and O’Malley suggest that the selection of studies based on inclusion and exclusion criteria may take place post hoc after sufficient familiarity with the literature is established. Levac proposes that the research team should determine study exclusion and inclusion criteria at the outset of the process, with the ability to refine the search strategy and review additional articles for inclusion if warranted.

As recommended, two reviewers will independently select all relevant studies; in cases of disagreement, a third reviewer will provide input. A two-level selection process will be used. First, articles will be screened by study title and abstract against the inclusion and exclusion criteria listed below and then read in full to ensure appropriateness for study inclusion.

Inclusion criteria

For studies to be included, they should meet the following criteria:

► Adult patient population.
► Includes hospital admission of any status (observation or inpatient status).
► Includes assessment of some additional factor other than medical acuity, including but not limited to: socioeconomic status, insurance status, barriers to healthcare access, lack of housing, food insecurity, mental health disorder, cognitive difficulties, physical disability or limitation, immigration status, non-English speakers.
► Empiric studies of any design type.
► Published either in peer-reviewed journals or in the ‘grey’ literature (conference proceedings, preprints and so on).

Exclusion criteria

Studies with the following criteria will be excluded:

► Not published in English.
► Primarily study inpatient psychiatric hospital admission.
► Commentaries, consensus statements or other non-empiric reports.

The process of study selection will be reported using a Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flowchart.

Stage 4: charting the data

Data will be extracted from each selected article using a standardised extraction template. Detailed description of data extraction fields is available in Table 1.

Overarching domains will include article characteristics, study design, characterisation of factor other than medical acuity and findings. Based on initial literature review, we predict that some studies will use collective or general terminology for factors unrelated to medical acuity (eg, ‘non-medical-acuity’, social factors or deprivation) while other studies will use specific, named factors such as homelessness. We will extract terminology used in either category as well as any definitions provided in the study for the terms used.
As the scoping review is intended to be an iterative template will be modified based on this pilot testing. Inter-rater reliability. If necessary, the data extraction full-text data extractor independently and compared for a sample of the included studies will be reviewed by each to ensure consistency in data extraction and coding. A trial of independent data extraction will be performed,15 a of extraction data fields. As suggested by Daudt et al be trained together to ensure collective understanding.

Team members serving as full-text data extractors will be trained together to ensure collective understanding of extraction data fields. As suggested by Daudt et al,15 a trial of independent data extraction will be performed to ensure consistency in data extraction and coding. A sample of the included studies will be reviewed by each full-text data extractor independently and compared for inter-rater reliability. If necessary, the data extraction template will be modified based on this pilot testing. As the scoping review is intended to be an iterative process, it is possible that additional themes will emerge and pertinent information will need to be added to the data extraction process. The research team will meet regularly to review progress and to discuss evolution of concepts. Any revisions to the data extraction process will be discussed collectively by all members of the research team.

While not a requirement of scoping reviews, the assessment of methodological quality is a hallmark of rigorous systematic reviews and will assist with the potential use of any findings that are reported. We will use the mixed-methods appraisal tool, which has been developed for complex systematic literature reviews such as this that combine qualitative, quantitative and mixed-methods studies.16 17

**Stage 5: collating, summarising and reporting the results**

Information extracted in stage 4 will be summarised in tabular format. Quantitative analysis will be performed to produce descriptive statistics summaising the data contained in domains of study design and characterisation of factor other than medical acuity.

Because one of our central questions is how terminology is used in this literature, we will map terms used in each of the categories (collective/general and specific). Two reviewers will independently map terms used in the studies to a list we have created based on preliminary literature review (those referenced in the inclusion criteria: socioeconomic status, insurance status, barriers to healthcare access, lack of housing, food insecurity, mental health disorder, cognitive difficulties, physical disability or limitation, immigration status, non-English speakers). This list may be expanded for any terms encountered that do not map specifically. Results will be compared and discussed among the group until consensus is achieved and may be displayed graphically (if appropriate) or summarised in narrative form.

In addition, we intend to provide narrative summary in answer to the other subquestions listed in stage 1 above related to perspectives investigated, type of research performed and findings. Ideally, we also plan to construct a conceptual model for broader use, though it is possible that findings will not be able to be unified in this manner. Results reported in a final manuscript will follow recommendations included in the PRISMA Extension for Scoping Reviews (PRISMA-ScR) checklist.18

**Stage 6: consultation**

Arksey and O’Malley suggest an optional final stage that includes consultation with stakeholders in order to add value and insight. Currently, we do not plan to formally include this step in the generation of a final product. Because this work has the potential to overlap with many aspects of research and clinical care, we anticipate that additional discussion and consultation will be completed with dissemination of the work at conferences and in publication.
PATIENT AND PUBLIC INVOLVEMENT

There was no patient or public involvement in the preparation of this protocol. We have included extraction of data related to perspectives identified in the literature and plan to incorporate discussion of patient perspective within the literature as a whole.

DISCUSSION

The protocol describes a comprehensive approach that will survey current literature to elucidate existing information and reveal gaps in knowledge regarding the contributors other than medical acuity to hospitalisation. The final review product aims to summarise the current field of knowledge with respect to factors investigated, methods designed, findings identified and nomenclature used. This overview will better equip practitioners and policymakers to contextualise hospitalisation decisions and will provide researchers more complete understanding of the landscape of this field. This study addresses an urgent need for enhancing understanding and may inform new studies or policy. Understanding the impact of these factors on hospitalisation has potentially broad implications for quality improvement efforts, healthcare funding models and population or public health initiatives at local, state, national and international levels.

Contributors

MB led the conceptualisation of the work. Both MH and MG contributed to the scope and design of the review as well as inclusion and exclusion criteria. MG prepared the manuscript for publication. MH designed the data extraction template. AM provided feedback on the methodology and crafted the criteria. MG prepared the manuscript for publication. MH designed the data

Funding

The authors have not declared a specific grant for this research from any funding agency in the public, commercial or not-for-profit sectors.

Competing interests

None declared.

Patient consent for publication

Not required.

Provenance and peer review

Not commissioned; externally peer reviewed.
