Objective	Conclusion	Method	Confounder adjustment	Estimates provided	Authors Considerations	
CONSISTENTLY CAUSAL						
“To evaluate the <b>impact</b> of [...] on [...] in [...]”	“[...] is associated with negative <b>effects</b> on [...]. Given the relatively low prevalence of [...], population level impacts are currently modest. Nevertheless, as [...] has doubled in the US over the past generation, further investigation is warranted of the <b>impact</b> on	“To estimate the <b>adjusted</b> odds ratio for each [...] outcome by [...] group, we created logistic regression models with [...] as the reference group. [...] The <b>population attributable risk</b> was calculated using the standard formula”	“Other subgroup analyses were done to ensure that [...] association was <b>not confounded</b> by [...]”	“[...] had 14% higher odds of [...] compared with [...] (adjusted odds ratio 1.14, 99% confidence interval 1.13 to 1.15). [...] 14.5% (13.6% to 15.4%) of [...] (under the assumption of a <b>causal</b> relation) can be <b>attributed</b> to [...]”	“The pooling of all [...] during this period minimizes the risk of <b>confounding</b> from yearly fluctuations in [...] outcomes. Finally, despite attempts to adjust [...] using regression analysis and stratification, some <b>residual confounding</b> effects from [...] could remain. [...] As more than 12% of [...] <b>might have been</b>	Both abstract and main text use causal language: they state that their aim is to assess the impact of the exposure on the outcome, adjust for confounders, provide population attributable risks and discuss residual confounding.

	[...] and public health.				<b>prevented</b> were [...], the importance of these data are most relevant to [...]. The cumulative risk over [...] is also likely to be <b>important in terms of both economic burden and overall public health</b> "	
"To examine the [...] <b>risks of [...]</b> <b>initiation</b> compared with initiation of other traditional [...] drugs, initiation of [...], and no initiation."	"[...] <b>poses a [...]</b> <b>risk</b> compared with non-use, [...] use, and use of other traditional [...] drugs."	"[W]e conducted a series of cohort studies, each mimicking the strict design criteria of a clinical trial (a so-called <b>emulated trial design</b> ), to compare rates of [...] among [...] with rates among [...]. [...] We estimated an observational analogue of the <b>intention to treat</b> hazard ratio, as a measure of the incidence rate ratio,	"We calculated the <b>propensity score</b> for all eligible individuals initiating [...] at enrolment by fitting a logistic regression model including covariates on sex, age, year, comorbidity, and	"[...] initiators had a 50% <b>increased rate of [...]</b> events compared with [...] non-initiators (incidence rate ratio 1.5, 95% confidence interval 1.4 to 1.7)."	"We performed the following sensitivity analyses, [...] to estimate how strongly a single <b>unmeasured confounder</b> would need to be associated with [...] to fully explain our	The use of causal language appears in both abstract and main text. They apply causal methods including target trial emulation and propensity

		by fitting a Cox proportional hazards model, using time since start of follow-up as the time scale and a time independent covariate for treatment assignment. We pooled data from all trials into one model and included each trial as a stratum in the regression (using values from 1 to 252).”	drug treatment use. We then <b>matched</b> non-initiators to [...] initiators (1:1) by <b>propensity score</b> within a maximum <b>matching</b> range of 0.025 and without replacement.”		findings. [...] Finally, an <b>unmeasured confounder</b> that was twice as frequent among [...] initiators versus among non-initiators would still need to increase the risk of [...] by a factor of nine or more to fully explain the results, if no increased risk actually existed (eFigure 3). [...] Still, the <b>emulated trial design</b> lacked baseline randomisation, and therefore, <b>unmeasured confounding</b> cannot be excluded.”	score matching and discuss residual confounding.

	early clinical intervention.”				residual confounding by other unmeasured covariates”	
“To investigate whether adults with [...] are at an increased risk of [...] and whether the risk varies by [...] severity and condition activity over time.”	“Severe and predominantly active [...] are associated with an increased risk of [...] outcomes. <b>Targeting [...] prevention strategies</b> among these patients should be considered.”	“We used Cox regression stratified by <b>matched</b> set [...] with current age as the underlying timescale to generate hazard ratios for the association between [...] and each [...] outcome (the unadjusted model). Subsequent multivariable analyses adjusted for [...] (the <b>adjusted</b> model). The adjusted model was further adjusted for variables which may have been on the <b>causal pathway</b> (ie, <b>mediators</b> ) between [...] and [...] outcomes [...] (the <b>mediation</b> model). [...] The <b>population attributable risk</b> of each [...] outcome was estimated by using the estimated hazard ratio	“For each patient with [...], we <b>randomly matched</b> up to five patients by age (within 15 years), sex, general practice, and calendar time at cohort entry. These unexposed patients were required to have at least one year of follow-up in CPRD and no history of [...] when matched. [...] We used a <b>directed acyclic graph</b> to inform the identification	“Table 3 shows that in the primary analysis, there was evidence of <b>associations</b> between [...] and all [...] outcomes, except for [...]. <b>Associations were strongest with [...]</b> (hazard ratio 1.25, 99% confidence interval 1.11 to 1.41 in the adjusted model) and [...] (1.19, 1.10 to 1.30), with <b>partial attenuation in the mediation model</b> . [...] The	“Limitations of the study, inherent to most large observational studies, include the possibility for <b>confounding</b> , bias, and missing data. [...] We <b>have shown a clinically relevant increase in the risk of [...]</b> outcomes in patients with [...]. This increased risk is largely confined to patients with severe or more active [...] and persists despite	The causal aim is evident in the abstract because they intend to assess how the risk of the outcome varies when the exposure is modified and the conclusion is to take action given the findings. The main text uses causal language, discusses DAGs, mediators, collider bias

		and assuming the prevalence of [...] to be 10%.”	of covariates and <b>mediators</b> and to avoid <b>collider bias</b> ”	greatest <b>population attributable risks</b> were estimated for [...] (2.4%, 1.1% to 3.9%) and [...] (1.9%, 1.0% to 2.9%).”	adjusting for potential mediators, including conventional risk factors for [...] outcomes. Consideration should be given to <b>developing prevention strategies to reduce the risk of [...]</b> among patients with severe or predominantly [...]”	and provides population attributable risks.
“To <b>determine the effect of [...]</b> outcome reporting in [...] on risk averse clinical practice, “gaming” of clinical data, and 90 day	“This study <b>did not find evidence that</b> the introduction of [...] in [...] <b>has led to risk</b> averse clinical practice behaviour or	“We used a <b>change point analysis</b> to study the change over time in <b>adjusted</b> 90 day mortality after [...] and after [...]. We used a multivariable logistic regression model for 90 day mortality, with a slope for calendar time and an interaction	“The <b>risk factors</b> included in this logistic regression model are [...]. An adjusted outcome was then produced by indirect <b>standardisation</b> ”	“The 90 day mortality in patients undergoing an [...] fell during the study period from 952/33 638 (2.8%) before the introduction of [...] to 552/25	“If we assume that the decrease in mortality can be <b>causally linked to [...]</b> , the process of [...] This team response could have been	Causal language is present in abstract and main text as they state that their aim is to determine the effect of the exposure on

postoperative mortality.”	“gaming” of data. However, <b>its introduction coincided with</b> a significant reduction in 90 day mortality.”	between time pre-introduction versus post-introduction of [...], in addition to all of the <b>risk adjustment variables</b> . This modelled a change in the slope of mortality at the point that [...] was introduced but no immediate change in mortality.”		905 (2.1%) after (fig 4). Therefore, we carried out change point analysis which showed a steeper decline in 90 day mortality after the introduction of [...] (P=0.03). The <b>change point analysis also found a significant effect of [...]</b> when it was modelled as an immediate shift in 90 day mortality (P=0.01) and when it was modelled as both an immediate shift and a change in slope (P=0.04).”	<b>mediated</b> through [...]”	the outcome and conclude that the exposure has not led to the outcome. The main text explains that confounder adjustment was made through standardisation and discuss possible mediators for this relationship.
“To assess the <b>effectiveness of</b>	“Little evidence was found of a	“We estimated one year <b>net survival</b> for each [...]	“Survival estimates for all	“One year survival	“The lack of <b>consistent</b> results	Causal language is

<p>the [...] policy initiatives in <b>improving</b> [...] <b>and reducing</b> [...] in survival in England.”</p>	<p><b>direct impact</b> of [...] on one year survival, and no evidence for a reduction in [...] in cancer survival. These findings emphasise that [...] in survival remain a major public health problem for a healthcare system founded on equity.”</p>	<p>by sex, year of diagnosis (1996 to 2013), and deprivation category. Patients with a diagnosis between 1996 and 2013 had the potential to be followed up for at least one year, so we used the classic cohort approach. [...] We estimated net survival using the consistent nonparametric estimator defined by Pohar-Perme.”</p>	<p>ages combined were age <b>standardised</b> with the International Cancer Survival Standard weights. [...] We used multivariable linear regression to investigate the survival patterns for each [...] and by sex”</p>	<p><b>improved</b> for 20 of the 21 [...] examined in women and 16 of the 20 [...] examined in men. [...] For these [...], the average annual absolute increase in one year age <b>standardised net survival</b> was often greater than 1% over the whole study period”</p>	<p>between men and women, as well as the lack of general patterns across [...] types, provide <b>little evidence for any strong impact</b> of the [...] policies on short term [...] survival. The evidence is even weaker for their <b>impact</b> on the [...] in [...] survival. [...] <b>These findings should be taken into consideration by</b> [...] policy makers and inform future initiatives.”</p>	<p>present in both abstract and main text. The aim is to evaluate the effectiveness of a policy on a given outcome, they provide standardised net survival and suggest to take action given the findings.</p>
--	--	---	--	---	--	---

<p>To investigate whether <b>improving</b> adherence to [...] <b>interacts with</b> the genetic predisposition to [...] in relation to long term changes in [...] and [...].”</p>	<p>“These data indicate that improving adherence to [...] could <b>attenuate</b> the genetic association with [...]. Moreover, the <b>beneficial effect</b> of improved [...] on [...] was particularly pronounced in people at high genetic risk for [...].</p>	<p>“We used multivariable generalized linear models with repeated measures analyses to assess the main <b>associations of the [...] and changes in the [...] with change in [...]</b>”</p>	<p>“We used multivariable models to <b>adjust for [...]</b>”</p>	<p>“In general, the [...] was <b>associated with increases in [...]</b> every four years: in the two cohorts combined, each additional [...] was associated with 0.02 (SE 0.01) increase in [...] and 0.05 (SE 0.03) kg increase in [...].”</p>	<p>“[...] <b>unmeasured or unknown confounders</b> may also exist. Secondly, because adherence to [...] was not randomized, the association between [...] and [...] may not imply a <b>causal relation</b>. Thirdly, the results could be underestimated by potential <b>reverse causality</b>. [...] Our study provides reproducible evidence from two prospective cohorts of US men and women that <b>improving [...] could attenuate</b> the [...].”</p>	<p>Assessing if improving adherence has an effect translates to an intervention that is being assessed. They conclude that there is a beneficial effect and suggest to take action. The main text discusses unmeasured confounding assumption and reverse causality. All of the above is consistent with a causal aim.</p>

People in	Patients and members of the comparison cohort were <b>well matched</b> with respect to [...] Mortality was not higher among patients in the [...] cohort"		The abstract states that they aim is to estimate survival but they use matching and conclude that the exposure has no 'substantial effect' on the outcome.

			the population comparison cohort were assigned the same date of study inclusion as [...] patients to whom they were <b>matched.</b> "			
"To <b>compare</b> the risk of [...]"	"Although <b>residual confounding</b> cannot be excluded, this finding deserves consideration when [...] is used for [...]"	"We estimated the crude hazard ratio of [...] using Cox proportional hazard regression, and the adjusted hazard ratio was obtained using <b>propensity score matching</b> "	" We identified <b>potential confounders</b> that were plausibly associated with both [...]based on clinical knowledge [...] In the context of this study, the propensity score is the probability of receiving [...] as opposed to [...], given the baseline characteristics. Patients who received [...]"	"The crude hazard ratio of death in the unmatched cohort was 1.51 (95% confidence interval 1.22 to 1.85) and the adjusted hazard ratio in the matched cohort was 1.50 (1.14 to 1.96)"	"Comparison of the baseline characteristics in the unmatched cohort provided little evidence of confounding [...] it is unlikely that a few additional <b>unmeasured</b> variables can explain a 50% increase in the risk independent of all other confounder and proxies of <b>confounders</b> that	The abstract suggests that they aim is comparison of the risks but does not explicitly use causal language. They do adjust for confounding, using propensity score matching, and discussed unmeasured confounding which are

			<p>were matched to patients who [...] using a 1:1 nearest neighbor matching algorithm with a caliper of 0.2 of the standard deviation of the propensity score on the logit scale. Covariate balance between the two groups was assessed after matching, and we considered an absolute standardized difference less than 0.1 as evidence of balance”</p>		<p>are adjusted for in our study.”</p>	<p>applied when aiming for causal inference.</p>
<p>“To <b>determine</b> whether [...] is associated with [...]”</p>	<p>“[...] was independently <b>associated</b> With [...]”</p>	<p>“We fitted both a mixed effect logistic regression model (in which the outcome was defined as</p>	<p>“We examined the relation between [...] and</p>	<p>“The rate of distinct criteria met per year increased by 24%</p>	<p>“We did a sensitivity analysis using <b>propensity score</b></p>	<p>The aim uses causal language but the conclusion</p>

		dichotomous [...] and the Prentice, Williams, and Peterson (PWP) model”	[...] <b>adjusted</b> for ...”	if a patient had been admitted to hospital (hazard ratio 1.24, 95% confidence interval 1.20 to 1.28) when <b>controlled</b> for the other covariates”	<b>matching</b> to assess whether the association between [...] and [...] could be due to <b>unmeasured confounders</b> [...] Although we adjusted for a range of characteristics of patients, as with any observational study potential exists for <b>unmeasured confounding</b> , which may partly or fully explain the relation between [...]”	is phrased in terms of association. They provide adjusted estimates, use propensity score as sensitivity analysis and discuss unmeasured confounders. The only reason to present a conservative conclusion seems to be the observational nature of the study.
“To investigate associations between [...] and to analyse the	“Risks of [...] are inversely <b>associated</b> with [...]”	“We used multivariable Cox regression analysis to <b>compare</b> the rates of [...] and [...]. “	“ <b>Confounders</b> included in the final models were based on the literature or	“Compared with [...], [...] had increased hazard ratios of [...]”	“We believe that our findings are widely applicable and provide justification for	The aim suggests a causal aim because they evaluate the

effect of changes [...]"			statistical significance ( $P < 0.10$ ). The full model included [...]"		[...] and continuing [...]"	impact of changing the exposure which makes it an intervention and they provide estimates adjusted for confounders. The conclusion is phrased in terms of association.
"To estimate the <b>rates of</b> [...]"	"In cases of [...], approximately [...] will become [...], of which a third will have [...]."	"We present denominators where data for the secondary outcome are missing. We defined the population <b>attributable fraction</b> as $(Re - R_{un}) / Re = (RR - 1) / RR$ , calculated using Stata. To test the robustness of our findings, we did a sensitivity analysis."	"We compared the demographic and clinical variables of [...]. We used the binomial Wilson score to calculate confidence intervals of single proportions and the Pearson exact method to calculate	"[...] had a higher risk of [...]. The population <b>attributable fraction</b> of [...] was 47% for [...] and 61% for [...]"	" Considering these results when <b>counselling</b> potentially exposed [...] seems reasonable"	The aim and conclusion are phrased in association terms. However, they estimate attributable fractions and suggest to act given the findings.

			confidence intervals of risk ratios and medians.”			
To perform an expedited <b>assessment of [...] risk</b> associated with exposure to [...]”.	“The results <b>do not imply</b> a markedly increased short term overall risk of [...] in [...].”	“We used Cox regression to estimate the hazard ratio with 95% confidence intervals for [...] associated with [...], both for ever use and for the predefined categories of cumulative use”	“Analyses were, however, performed as crude comparisons <b>adjusted</b> only for [...] as well as adjusted for [...] and the <b>potential confounding</b> factors.”	“Overall, exposure to [...] showed no association with [...] compared with exposure to [...] (adjusted hazard ratio 1.09, 95% confidence interval 0.85 to 1.41) and no evidence of a dose-response relation”	“This ensured that the estimates were not affected by <b>immortal time bias</b> [...]. As all comparisons were performed within users of [...], the exposure to [...] can reasonably be expected to be a random event, and <b>confounding</b> is thus expected to be limited.”	The aim does not use causal language. They do provide estimates adjusted for confounding, discuss immortal time bias and conclude that the exposure does not result in an increase survival.
“To investigate the <b>risks</b> of [...] in [...]”	“No increased risk of [...] was detected in [...], but increased risks of [...] were found in this study. Our	“To calculate expected [...], we multiplied the person years at risk by corresponding national incidence rates (by 5 year age band and individual calendar year) for the	“We obtained data relating to <b>potential confounding</b> factors such as [...]”	“There was no overall increased risk of [...] (2578 observed v 2641.2 expected [...]; standardised incidence ratio	“Given previous inconsistent results, small study size, and lack of information on <b>potential</b>	The aim does not use causal language. They provide standardised estimates, discuss

	results suggest that [...] <b>risks could be due to [...], rather than [...].</b> "	general female population of England and Wales. <b>Standardised incidence ratios</b> were calculated by the comparison of observed values with expected values."		0.98 (95% confidence interval 0.94 to 1.01); absolute excess risk -2.8 cases per 100 000 person years (95% confidence interval -7.1 to 1.8); table 2)".	<b>confounders</b> , we undertook a population based linkage study in [...]"	confounding and conclude that the risk of the outcome is due to a given exposure compared to another.
CONSISTENTLY NOT CAUSAL						
"To determine whether [...], compared [...], is <b>associated</b> with an increased risk of [...]"	"In this population based cohort study, [...] was <b>associated</b> with an increased risk of [...]. The association was particularly elevated among people using [...] for more than five years. <b>Additional studies</b> , with	"We calculated crude incidence rates of [...] and 95% confidence intervals, based on the Poisson distribution, for each exposure group. We used time dependent Cox proportional hazards models to estimate hazard ratios and 95% confidence intervals of [...] associated with [...] compared with [...], using multiple imputation for variables with missing values."	"Potential <b>confounders</b> . All models were <b>adjusted</b> for the following variables measured at cohort entry: [...]. [...] as an alternate means of controlling for <b>confounding</b> , we repeated the analysis by stratifying the model on tenths	"Compared with [...], [...] were <b>associated</b> with an overall 14% <b>greater risk of</b> [...] (1.6 v 1.2 per 1000 person years; hazard ratio 1.14, 95% confidence interval 1.01 to 1.29)."	"We introduced a one year exposure lag period to account for a minimum latency time window and to minimize <b>reverse causality</b> . [...]The association between [...] and [...] is <b>biologically plausible</b> . [...] although we were able to adjust for several	In the abstract they only describe associations but in the full text their interest points to a causal aim given the different methods applied to adjust for confounding and reverse causality. They

	long term follow-up, are needed to investigate the <b>effects</b> of [...] on [...].”		of disease risk score. Finally, we repeated the analysis using a <b>marginal structural</b> Cox proportional hazards model using <b>inverse probability of treatment</b> and censoring weighting—a method designed to adjust for time dependent <b>confounding</b> associated with time varying exposures”		important <b>confounders</b> , this study lacked information on other potential <b>confounders</b> such as [...] In this large, population based study, [...] was associated with an elevated risk of [...] overall, along with evidence of a <b>duration-response relation.</b> ”	also consider elements as biologically plausibility and duration response relation. Residual confounding seems to be a concern because they lacked information on relevant cofounders which could lead to down tone of the conclusions.
“To determine whether [...] and [...] are <b>associated</b> with an <b>increased risk</b> of [...] in adults with [...].”	“Compared with [...], [...], and [...], <b>might be associated</b> with an increased risk of [...] in adults with [...].”	“For each exposure category we calculated crude incidence rates of [...] with 95% confidence intervals, based on the Poisson distribution. Time dependent Cox proportional hazards	“The models were <b>adjusted</b> for the potential <b>confounders</b> measured at cohort entry: [...] To minimise potential	“Compared with [...], [...] was <b>associated</b> with a 77% increase in the hazards of [...] (hazard ratio 1.77, 95% confidence	“Finally, we excluded those with less than one year of follow-up after cohort entry, to allow for a sufficient latency	The abstract only refers to association but the full text mentions adjusting for confounders and ways to

		models were used to estimate hazard ratios and 95% confidence intervals of [...] associated with [...] and [...], separately, when compared with [...].”	<b>confounding</b> by indication, we compared [...]. [...] we fit a <b>marginal structural model</b> to investigate the impact of potential time dependent <b>confounding</b> using <b>inverse probability of treatment</b> and censoring weighting.”	interval 1.04 to 3.01).”	period and to minimise <b>reverse causality</b> . [...] To assess possible <b>duration-response relations</b> , we investigated the association between cumulative duration of [...] on the risk of [...]. An association between [...] and incidence of [...] is <b>biologically plausible</b> . [...] as with all observational studies, <b>residual confounding</b> is possible. We conducted several sensitivity and ancillary analyses specifically designed to	minimise reverse causality. They also describe its biological plausibility. There is a concern for residual confounding due to the observational nature rather than missing information on particular relevant confounders.

We calculated total person years of observation in each age and sex stratum for each year.”	“The age and sex <b>adjusted</b> rate of [...] increased from 14 869 tests per 10 000 person years in 2000/1 to 49 267 in 2015/16 (table 1, fig 1), an annual increase of 8.5% (95% confidence	“We analysed the temporal change in [...] from UK primary care. The total use of tests increased markedly over time, even after adjustment for population growth”	The abstract and full text state that they aim to quantify changes of a condition over time. It is a descriptive study that does not use causal

	significantly over time.”			interval 7.6% to 9.3%). [...] The slope of the trend line changed significantly at two points: 2004/5 (P<0.001) and 2008/9 (P=0.004) (fig 1).”		language accordingly.
“To investigate the <b>association</b> of [...] with disease specific incidence and mortality and whether [...] enhances the <b>prediction</b> ability of an established office based <b>risk score</b> .”	“[...] was <b>associated</b> with a range of health outcomes and improved <b>prediction</b> of an office based <b>risk score</b> . Further work on the use of [...] in risk scores or risk screening is needed to establish its potential clinical utility.”	“[...] we investigated the associations of [...] with cause specific incidence and mortality over follow-up with Cox proportional hazard models. We reported the results as hazard ratios together with 95% confidence intervals.”	“We treated [...] as potential <b>confounders</b> . For Cox proportional hazard analyses, we ran four models that included an increasing number of covariates: model 0 (minimally adjusted) included [...]”	“As shown in figure 1, in both men and women, [...] was <b>associated</b> with a higher hazard for all cause mortality and incidence of and mortality from [...] in model 0. The <b>associations</b> were similar after <b>adjustment</b> for [...] in model 1; after further adjustment, the magnitude of	“To minimise the potential contribution of <b>reverse causality</b> to the findings, we did a landmark analysis excluding events occurring within the two years after recruitment in model 4 (landmark analysis). This landmark analysis was adjusted as in	The abstract mentions associations and suggests that the aim is prediction. In the main text, the authors conclude that the exposure of interest enhances prediction and identification of patients with risk of certain diseases.

				<p>associations were slightly attenuated in models 2, 3, and 4”</p>	<p>model 3. [...] may, therefore, be a useful method of <b>identifying</b> people with [...] who are at high risk of a wide range of diseases. [...] <b>Reverse causality</b> is possible in any observational study. [...] Similarly, <b>residual confounding</b> is always possible and the associations observed may not imply <b>causality</b>. However, given that we are largely interested in <b>prediction</b> and identification of people at</p>	<p>However, there is use of causal language, including confounder adjustment and discussing reverse causality and residual confounding. They note that their goal is to do prediction and that reverse causality is not a major limitation but still adjust for it.</p>

					increased risk, and not seeking to make strong causal inferences, <b>reverse causality</b> is not a major limitation.”	
“To <b>externally validate</b> four commonly used rules in [...] for [...].”	“Application of the [...] rules can lead to a wide variation in [...] among patients with [...], <b>resulting</b> in many unnecessary [...] findings. Until an existing decision rule has been updated, any of the four rules can be used for patients presenting [...] at the	“The sensitivity, specificity, and proportion of patients [...] (with 95% confidence intervals) were assessed for each of the four decision rules. [...] The Cochran’s Q test was used to directly compare the sensitivities and specificities between the four decision rules [...]. Net proportional benefit has been proposed to incorporate such weighting in calculation of clinical usefulness of decision rules. For each rule, we expressed the net proportional benefit using the formula: (true	--	“The sensitivity for identifying patients with [...] ranged from 72.5% for the [...] criteria to 98.8% for the [...] rule (table 4; appendix 3). [...] The [...] criteria would have missed 11 of 74 patients with [...] (appendix 4). The CHIP criteria would have missed two patients with [...], who both had [...]. The	--	Both the abstract and the full text state that they aim to validate four decision rules for a particular condition. They compared the tests in terms of sensibility or specificity and concluded that the tests are similar and recommended the use of a particular one

	emergency department. Use of the [...] rule is recommended because it <b>leads to a substantial reduction in [...]</b> while missing few potential [...].”	positives/total number) – weight × (false positives/total number). ”		specificity for identifying [...] was lowest for the [...] rule (4.4%) and highest for the [...] criteria (60.9%). [...] The sensitivity and specificity differed significantly between all the rules (Cochran’s Q P<0.001). ”		given that it can help avoid false negatives. The wording ‘resulting’ and ‘leads to’ are in fact to discuss the potential for false positives/false negatives rather than a casual claim.
“To develop and <b>validate</b> a set of practical <b>prediction tools</b> that reliably estimate the outcome of [...].”	“The <b>prediction</b> models reliably estimate the outcome of patients who were managed in various settings for [...]. The <b>predictor</b> items are readily derived at hospital admission. The	“The <b>association</b> between predictor variables and [...] was analysed by fitting proportional odds logistic regression models <b>adjusting</b> for the fixed effect of study. Prognostic strength was quantified as odds ratios with 95% confidence intervals. The relative importance of each <b>predictor</b> in the models was estimated	“In a published systematic review, we identified relevant <b>predictors</b> of outcome in patients [...]. Based on the results of this published review, we selected the following	“Bootstrap resampling showed negligible model optimism. The models had <b>internally validated AUCs</b> between 0.77 and 0.83. There was no significant lack of fit (goodness of fit	--	The abstract and main text state that the goal of the study is to validate a prediction tool. Consistent with the prediction aim, no causal

	web based [...] <b>prognostic</b> calculator [...] and the related app could be adjunctive tools to support management of patients.”	with partial R2 statistic, which estimates the independent <b>contribution</b> of the <b>predictor</b> to the variance of the outcome”	<b>predictor</b> variables that are assessable early at hospital admission and are consistently associated with outcomes for inclusion in the <b>prediction</b> models: [...]”	P≥0.2 in all models). Cross validated performance was variable across studies [...]. The partial R2 values ranged between 4% and 46%, and the pooled AUC values were between 0.74 and 0.77”		language is used.
“To prospectively <b>validate</b> [...] to triage patients with [...] in routine clinical practice.”	“In a population of patients referred for [...], this new triaging approach accurately <b>classified</b> [...] for most, with half the utilisation of ABPM compared with usual care. This	“To examine model performance, we constructed a logistic regression model with true [...] as the dependant outcome variable and classification using [...] as the independent predictor variable. From this model we estimated the <b>area under the receiver operating characteristic (AUROC) curve</b> statistic.”	--	“The triaging strategy [...] predicted true [...] (true positives 66%, 95% confidence interval 63% to 69%; true negatives 24%, 22% to 27%) with a low error rate (false positives 8%, 6% to 10%; false negatives 2%, 1% to 3%)	--	The abstract and main text describe that the aim is to validate a triage tool and assessed its performance compared to the standard of reference. As the aim is prediction, no causal language is

	triaging strategy can therefore be recommended for diagnosis or management of [...] in patients where [...] is being considered, particularly in settings with limited resources.”			(table 2). The triaging strategy resulted in 49% (46% to 52%) being referred for [...] and the remainder managed on the basis of their clinic measurements.”		used accordingly.
